CWFIS GeoNetwork catalogue (PROD)

Precipitation - FWI1987

This map displays 24-hour accumulated precipitation at local noon. Because Canada covers several time zones, local noon occurs at different times in different parts of the country. Precipitation values are interpolated between weather stations. Precipitation amounts can vary significantly over short distances; therefore, this map is accurate only at weather station locations and gives a general indication of precipitation conditions elsewhere.

Three different datasets are used depending on the retrieval time and when maps are updated daily. Details on the datasets and other information is found in the parent document, "Canadian Forest Fire Weather Index (FWI) System -- Daily Maps", linked above, and in Supplemental Information below.

Supplemental Information

Maps are updated daily shortly after 4 p.m., 5 p.m., and 6 p.m. Mountain Standard Time.

Precipitation:

Inputs to the FWI 1987 System include elevation and current daily weather data from a variety of sources. Local noon precipitation data is one of the four basic weather inputs into the FWI system (Canadian Forest Fire Weather Index (FWI) System - Daily Maps). Input weather data are included in the database holding FWI calculations done at weather stations, and from this, Geographic Information Systems (GIS) software interpolates the weather data between stations to produce gridded weather maps. The FWI System components are then calculated on a cell-by-cell basis according to the equations in Van Wagner and Pickett (1985) to produce the FWI maps.

Observed Weather Data Sources:

The CWFIS currently uses weather data from approximately 2500 stations in Canada and the United States. About 900 of these stations are operated by Environment and Climate Change Canada (ECCC) or other federal departments under contract to ECCC. About 600 stations are operated by the National Weather Service (NWS) of the United States are included (a subset of the total number), and the remainder of the stations are operated by the provincial and territorial governments.

The online data mart managed by ECCC provides a source for many observations from stations operated by various agencies, including other nations. While data from provincial and territorial wildland fire management programs are obtained through their own sources, observed weather without Fire Weather Index outputs for Atlantic Canada are downloaded from the ECCC data mart.

Forecast Weather Data Sources:

Forecasted weather used in the Canadian Wildland Fire Information System is provided by the Canadian Meteorological Centre, a branch of Environment and Climate Change Canada. Forecasted weather data can be found at the Meteorological Service of Canada Datamart (https://dd.weather.gc.ca/). These data take the form of spot forecasts for 845 Canadian weather stations or sample points. Weather elements are generated from the regional Global Environmental Multiscale (GEM) model and model output statistics (MOS) for three-hour intervals out to 48 hours. Noon weather is then interpolated from these data and fire danger indexes are calculated. The spot forecasts are straight model outputs or statistically post-processed data and do not include input from regional forecast offices.

Extended forecasts are based upon the North American Ensemble Forecast System (NAEFS), in which Canadian and American models contribute repeated forecasts with different initial conditions or physics packages. Median values of the 40-member ensemble are used to predict temperature, humidity, wind speed, and 24-hour precipitation at more than 250 weather stations for the next 14 days. These values are used to generate the extended forecast maps and the predicted fire weather conditions. Accuracy is limited because of the range of these forecasts. These forecasts are best used to judge the trend of long-term indices such as the duff moisture code (DMC), the drought code (DC), and the build-up index (BUI).
